

These areas were chosen as they had continued noise levels throughout the day. Ranging from quite-semi busy- and busy areas. The data allows one to see a rough average of the site and understand the effect noise might have within the site. Using data from <http://www.extrium.co.uk>, an overall idea was gathered to find the three areas as shown on the map.

Fann street was chosen as it had noise levels ranging from 35-70 (DB). The area went into the golden lane estate and ran onto the main road Goswell road as well as Fann street. This allowed us to test levels within a semi-busy area as it contains a residential section as well as a main road. The data varied in size and gave us an understanding of how a main road might effect a residential space

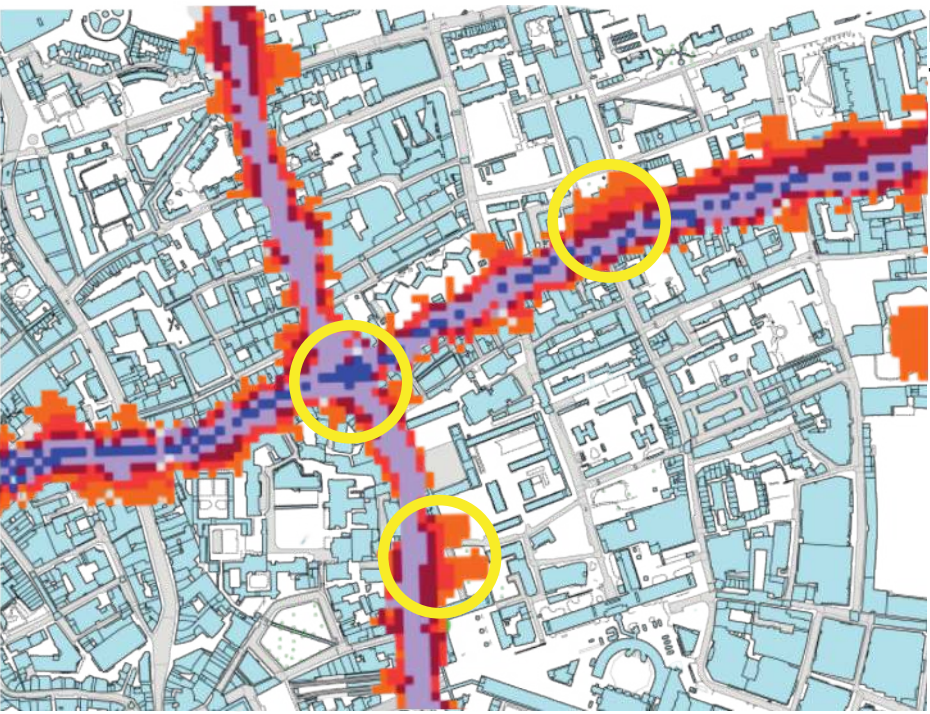

Clerkenwell road and Goswell Road inter-section was chosen as it had average noise levels ranging from 55- 70 (DB) and over. This area allowed us to test levels where noise would be constant and loud. The area was busy throughout the day, with foot traffic and transport traffic using the main roads to get to their desired destinations. It allowed us to test high noise levels within the site and how intersections might affect the areas they are in.

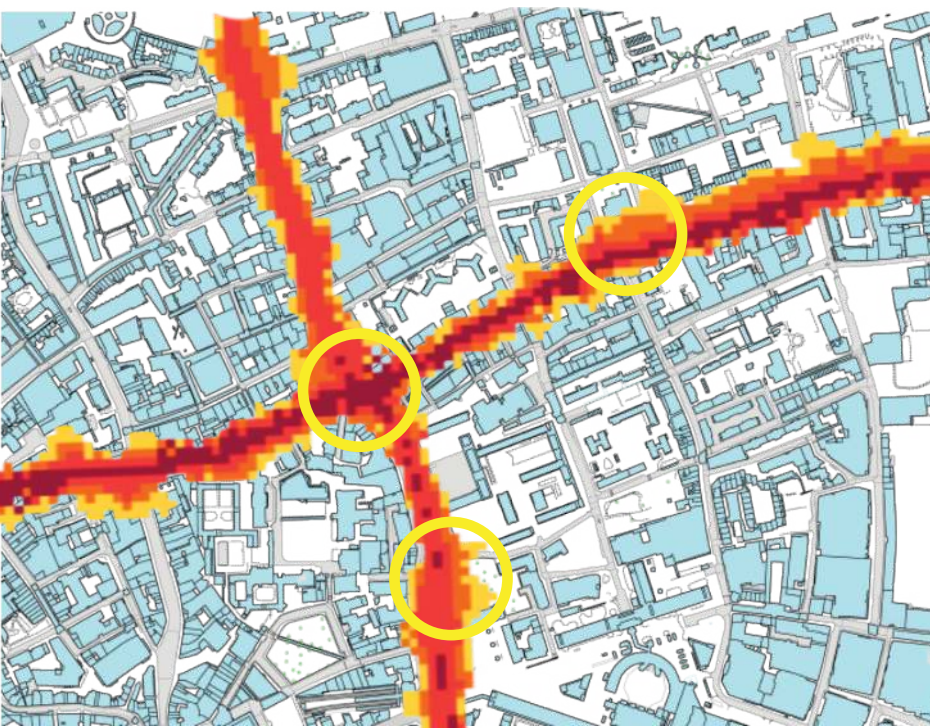

St Lukes, chosen as it is a quitter area, with the high levels coming from the Old street, having an average of 55-65 (DB). This area allowed us to test lower noise levels within the site. St Lukes has a park and residential buildings with the higher decibel levels coming from the main road or traffic passing through the area, giving one an example of a quitter area within the site and how a more seclude area might be effected by noise.

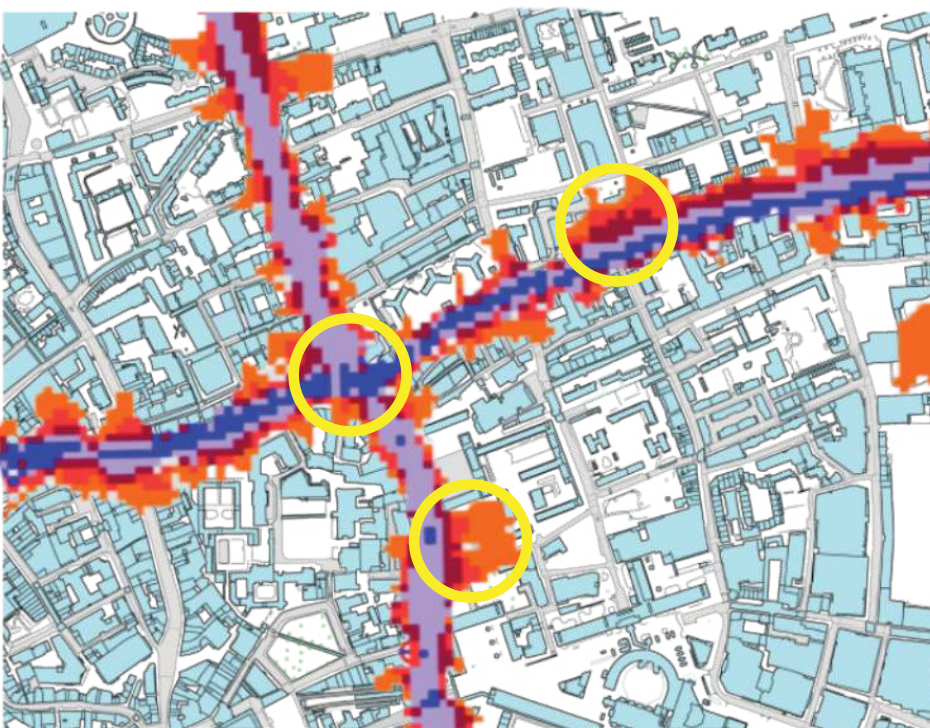

Changes

Day
7h-23h

Night 23h-7h

All day 24hrs

Areas of choice

Average noise level (dB)
70.0 and over
65.0 - 69.9
60.0 - 64.9
55.0 - 59.9
50.0 - 54.9
