

South - East Axonometric view showing direction of wind speed.

Further analysis was done of the environment using IESVE. From the analysis we can understand that the site has a wind speed between 1.5 m/s to 5 m/s depending on the location. Downdraft effect is created from the building opposite having approx. wind speed of 7m/s. Therefore, the heights of the buildings did affect the direction of the wind. The buildings surrounding the site created a barrier in the center. However, from the results obtained during analysis, there wasn't strong winds on the day except for the down draft bursts of wind.
